DENOSUMAB, WITH AND WITHOUT BIOLOGIC THERAPY AND THE RISK OF INFECTION IN PATIENTS WITH RHEUMATOID ARTHRITIS

INTRODUCTION: The use of biologic agents (BA) in the of rheumatoid arthritis (RA) have increased the risk of of infections, non-opportunistic as well as opportuni introduction of denosumab, a monoclonal antibody targ RANK ligand, has been associated with a possible risk of infection. As denosumab has a different th objective, specifically prevention of bone loss, it may b conjunction with other biologic agents raising the infections in patient with RA.

OBJECTIVES: To evaluate the risk of infection in patients with RA treated with denosumab alone or concomitantly with a biologic agent (BA).

METHODS: Patients with RA followed at the Institut de Rhumatologie de Montréal and who were prescribed denosumab were followed prospectively between February 2005 and July 2014. Baseline demographics, co-morbidities, co-medication and infectious events were recorded in the RHUMADATA® database. Patients were divided in 2 groups, the first received denosumab concomitantly with a biologic agent and the second group took only denosumab without ever taking a BA. The rate of infection was evaluated one year prior to the initiation of the denosumab and compared to the rate of infection during the exposure to denosumab in both groups. The data were analyzed using the SAS statistical software (Version 9.3).

> **RESULTS:** A total of 63 patients were ever prescribed denosumab, 20 concomitantly with a BA and 43 without a BA. Patients were on average 70.3 years of age, 92% were women, and had a mean (SD) RA disease duration of 18.6(13.5) years. Exposure to denosumab was on average 1.9 years for Group 1 and 1.6 years for Group 2. No differences were noted for co-morbidities or co-medication between the 2 groups. For Group 1, the rates of infections per 100 pt.-years were respectively 35.0 in the year preceding the start of denosumab and 15.7 during the concomitant use with a BA (p=0.16). For Group 2 the rates were respectively 18.6 prior to denosumab use and 25.0 during denosumab use (p=0.49).

> **CONCLUSIONS** In this cohort of RA patients whose baseline characteristics were similar, the risk of any infection was not increased by denosumab given alone or in combination with a biologic agent.
